Week Nine Exercise – Finding and Fixing PHP Errors

Name: Kena Patel

Error 1 – Line 13

Incorrect code: `<php`

Correction: `<?php`

Explanation: We need to write `<?php` to start PHP code.

Error 2 – Line 14

Incorrect code: `require(connect.php)`

Correction: `require("connect.php");`

Explanation: The file name should be inside quotation marks, and we need a semicolon at the end.

Error 3 – Line 15

Incorrect code: `/ This code has 10 errors.`

Correction: `// This code has 10 errors.`

Explanation: We need two forward slashes to write a comment in PHP.

Error 4 – Line 17

Incorrect code: `if (isset ($Name)`

Correction: `if (isset($name))`

Explanation: The variable should be `$name` because PHP treats uppercase and lowercase letters differently. We also need closing parenthesis.

Error 5 – Line 19

Incorrect code: Curly quotation marks around `Client Table`.

Correction: Use backticks around the table name: `` `Client Table` ``

Explanation: We should use backticks for a table name that contains a space.

Error 6 – Line 20

Incorrect code: `mysqli_query($con, $sql)`

Correction: `mysqli_query($con, $sql);`

Explanation: We need a semicolon at the end of this statement.

Error 7 – Line 21

Incorrect code: `mysql_num_rows($result)`

Correction: `mysqli_num_rows($result);`

Explanation: Since the code uses MySQLi, we should use `mysqli_num_rows()` instead.

Error 8 – Line 22

Incorrect code: `if($rows = 1)`

Correction: `if($rows == 1)`

Explanation: We need two equal signs to check if the number of rows is equal to 1.

Error 9 – Line 24

Incorrect code: `echo name;`

Correction: `echo $name;`

Explanation: We need to add `$` before the variable name because that is how PHP variables are written.

Error 10 – After line 24

Incorrect code: Missing closing curly braces.

Correction: Add another } before ?>.

Explanation: We need to close the outer statement with a closing curly brace.
